

Appendix

Table S1. Studies of the entomosarcosaprophagous fauna in the Mediterranean biogeographical region and the Iberian Peninsula, and the taxa studied in each work.....	1
Table S2. Abundance of all the taxa during the seasons and classification of the different taxa according to the different ecological groups (NC: necrophagous, NF: necrophilic, OM: omnivorous, OP: opportunistic, AC: accidental, ni: unidentified).....	2
Table S3. SIMPER analysis results when comparing the decomposition stages.....	4
Table S4. SIMPER analysis results when comparing the four seasons.....	10
Dynamic of the entomosarcosaprophagous community.....	14
Figure S1. Abundance and dynamic of the family Calliphoridae, <i>Musca domestica</i> , family Dermestidae, Histeridae and Formicidae during the four sampling seasons.....	16

Table S1. Studies of the entomosarcosaprophagous fauna in the Mediterranean biogeographical region and the Iberian Peninsula, and the taxa studied in each work.

Taxa studied	Family	Mediterranean biogeographical region and Iberian Peninsula studies
Entire community		Tantawi <i>et al.</i> , 1996; Arnaldos-Sanabria, 2000; Arnaldos <i>et al.</i> , 2004, 2005; Castillo-Miralbes, 2002; García-Rojo, 2004; García Rojo <i>et al.</i> , 2009; Bonacci <i>et al.</i> , 2010; Pérez Bote <i>et al.</i> , 2012; Baz <i>et al.</i> , 2015; Begoña Gaminde, 2015; López Gallego, 2016; Pérez-Marcos <i>et al.</i> , 2016; Díaz-Aranda <i>et al.</i> , 2018; Martín-Vega <i>et al.</i> , 2019; Muñoz-Lozano <i>et al.</i> , 2019
Diptera	Diptera (all) community	Martínez-Sánchez <i>et al.</i> , 2000; Arnaldos <i>et al.</i> , 2001; Campobasso <i>et al.</i> , 2001; Martínez Sánchez, 2003; Prado e Castro <i>et al.</i> , 2011b, 2012; Martín Vega, 2011; Martín-Vega and Baz, 2013; Bonacci <i>et al.</i> , 2014; Farinha <i>et al.</i> , 2014
	Calliphoridae	Dominguez Martinez and Gómez Fernández, 1963; Martínez-Sánchez <i>et al.</i> , 1998; Baz <i>et al.</i> , 2007; Bonacci <i>et al.</i> , 2009; Prado e Castro and García, 2009; Saloña-Bordas <i>et al.</i> , 2009; Prado e Castro <i>et al.</i> , 2011a, Velásquez <i>et al.</i> , 2011
	Phoridae	Campobasso <i>et al.</i> , 2004
	Piophilidae	Prado e Castro and García, 2010
	Sarcophagidae	Prado e Castro <i>et al.</i> , 2010
Formicidae	Sphaeroceridae	Arnaldos <i>et al.</i> , 2014
		Martínez <i>et al.</i> , 2002; Bonacci <i>et al.</i> , 2011; Prado e Castro <i>et al.</i> , 2014; Neto-Silva <i>et al.</i> , 2017; Pérez-Marcos <i>et al.</i> , 2020
Coleoptera	Dermestidae	Prado e Castro <i>et al.</i> , 2013
		Martín-Vega and Baz, 2010; Bonacci <i>et al.</i> , 2017

Table S2. Abundance of all the taxa during the seasons and classification of the different taxa according to the different ecological groups (NC: necrophagous, NF: necrophilic, OM: omnivorous, OP: opportunistic, AC: accidental, ni: unidentified).

Order	Family	Species	Ecological group	Season				Total %

Dynamic of the entomosarcosaprophagous community

1. Order Diptera

Adults of the order Diptera were dominant in abundance in all the studied seasons, meanwhile its larvae were the most abundant preimaginal in spring, winter and autumn. Among families of this order, Calliphoridae accounted for 65.19% of the total sarcosaprophagous adults recollected. Next, but with a much lower abundance, was Muscidae, representing 16.07%, and the Sphaeroceridae family with 5.88%, meanwhile other Diptera families represented less than 2.38% of the total (Table S2, Figure S1).

1.1. Family Calliphoridae

Chrysomya albiceps (Wiedemann 1819) was the most abundant species (58.15% of the total adults collected) and was present in the four seasons. It constitutes the predominant species during the autumn and summer, when it was collected since the bloated stage. In both seasons, a second peak of abundance was observed during the dry remains stage, corresponding to the emergence of the generation bred in the corpse. During winter and spring, *C. albiceps* was collected since the decomposition stage and the maximum abundance was reached during late decomposition (Figure S1).

Calliphora vicina Robineau-Desvoidy 1830 and *Calliphora vomitoria* (L. 1758), with 3.98% and 2.31% of the total adults, respectively, were mainly represented in the colder seasons, winter and spring, when they reached their maximum abundance in the decomposition stage. During the autumn, *C. vicina* and *C. vomitoria* were collected in very low numbers and, in summer, their presence was vestigial and null, respectively.

The rest of species (*Pollenia* sp., *Lucilia sericata* (Meigen 1826), *Lucilia* sp. and *L. caesar* (L. 1758)) were registered with an even lower abundance (Table S2, Figure S1).

1.2. Family Muscidae

Musca domestica Linnaeus, 1758 was the most abundant species (15.55%), collected mainly during the warmer seasons of autumn and summer, appearing in both cases since the bloated stage (Figure S1).

The rest of species, *Muscina stabulans* Fallen 1817, *Muscina levida* (Harrys 1780), *Hydrotaea meridionalis* Portschinsky 1882 and *Muscina prolapta* (Harrys 1780), were collected with a markedly lower abundance (Table S2, Figure S1).

1.3. Other Diptera families of forensic interest

Sphaeroceridae, Phoridae and Sarcophagidae families had a smaller representation, although they appeared in all seasons. The Sphaeroceridae had its biggest presence in spring. The Phoridae showed similar abundances in the four seasons, although it was slightly more abundant also in spring. However, it should be emphasized that the latter was the second in abundance of all the registered families during the winter, when it appeared from the fresh stage (Table S2, Figure S1).

Finally, the Sarcophagidae family deserves a mention for its recognized forensic interest, although in our case it did not reach significant abundances (0.51% of the total adults). It was present with similar abundance in summer, autumn and spring, being only symbolic in winter (Table S2, Figure S1).

2. Order Coleoptera

Coleoptera adults constituted the second order in abundance in winter and spring, and their larvae were the most abundant preimaginaries in summer. Within this order, the most abundant family was Dermestidae (1.37% of the total adults registered in the study), followed by the families Histeridae (1.11%) and Staphylinidae (0.34%). The remaining families showed less than 0.46% of the total abundance (Table S2, Figure S1).

2.1. Family Dermestidae

This family reached its highest abundance in winter. The most representative species was *Dermestes frischii* Kugelann 1792 (1.29%), distributed among the four seasons, appearing from the decomposition stage in autumn and summer and from the late decomposition in winter and spring, being always most abundant in the dry remains (Table S2, Figure S1). *Dermestes undulatus* Brahm 1790 was the second one, with a 0.07%, while the remaining specimens of this family were collected in even lower abundance. The dermestid larvae stand out for their relative abundance (1,562 individuals). They appeared only in the dry remains stage, except in the case of summer when they also appeared in the late decomposition. However, it should be noted that the appearance of larvae in winter was scarce (Table S2, Figure S1).

2.2. Family Histeridae

The predominant species was *Saprinus detersus* (Illiger 1807). Its greatest abundance was observed during the winter, closely followed by the spring, and its presence was more important during the late decomposition and the dry

remains stage. The other species found in this family had lower abundances, some of them being represented by only one specimen (Table S2, Figure S1).

2.3. Other Coleoptera families of forensic interest

Our results place the Staphylinidae family as the third most abundant among Coleoptera. *Creophilus maxillosus* (L. 1758), the most abundant species within this family, was usually present from decomposition stage onwards, being much less abundant in summer (Table S2). As a general rule, the rest of Coleoptera had a very low abundance and were mainly found during the most advanced decomposition stages (Table S2, Figure S1).

3. Order Hymenoptera

It was recorded more abundantly in autumn, and with very low abundances in winter (just 4 individuals). The taxa presented in our samples belonged to the superfamily Chalcidoidea (3.89%) and family Formicidae (1.88%), followed in much lower abundance by the families Vespidae and Apidae (less than the 0.27% of the whole adult sarcosaprophagous community) (Table S2, Figure S1).

3.1. Superfamily Chalcidoidea

In general, they were usually associated with the dry remains stage mainly in autumn and summer (Table S2, Figure S1). It should be noted that during the dry remains stage of the autumn, 1,172 individuals of this group were collected exclusively on day 37 (Table S2, Figure S1).

3.2. Family Formicidae

None of the species of this family seemed to be associated with any particular decomposition stage, although they presented its highest number of individuals in the dry remains. Formicidae specimens were collected in all seasons but they were much less abundant in winter (Figure S1).

Camponotus sylvaticus (Olivier 1792) was the most abundant species in all seasons, being present from the first few days until the end of sampling. It was followed in abundance by *Iberoformica subrufa* Roger 1859 and *Pheidole pallidula* (Nylander 1849) (Table S2). The remaining species were collected in very low numbers (Table S2, Figure S1).

Figure S1. Abundance and dynamic of the family Calliphoridae, *Musca domestica*, family Dermestidae, Histeridae and Formicidae during the four sampling seasons.

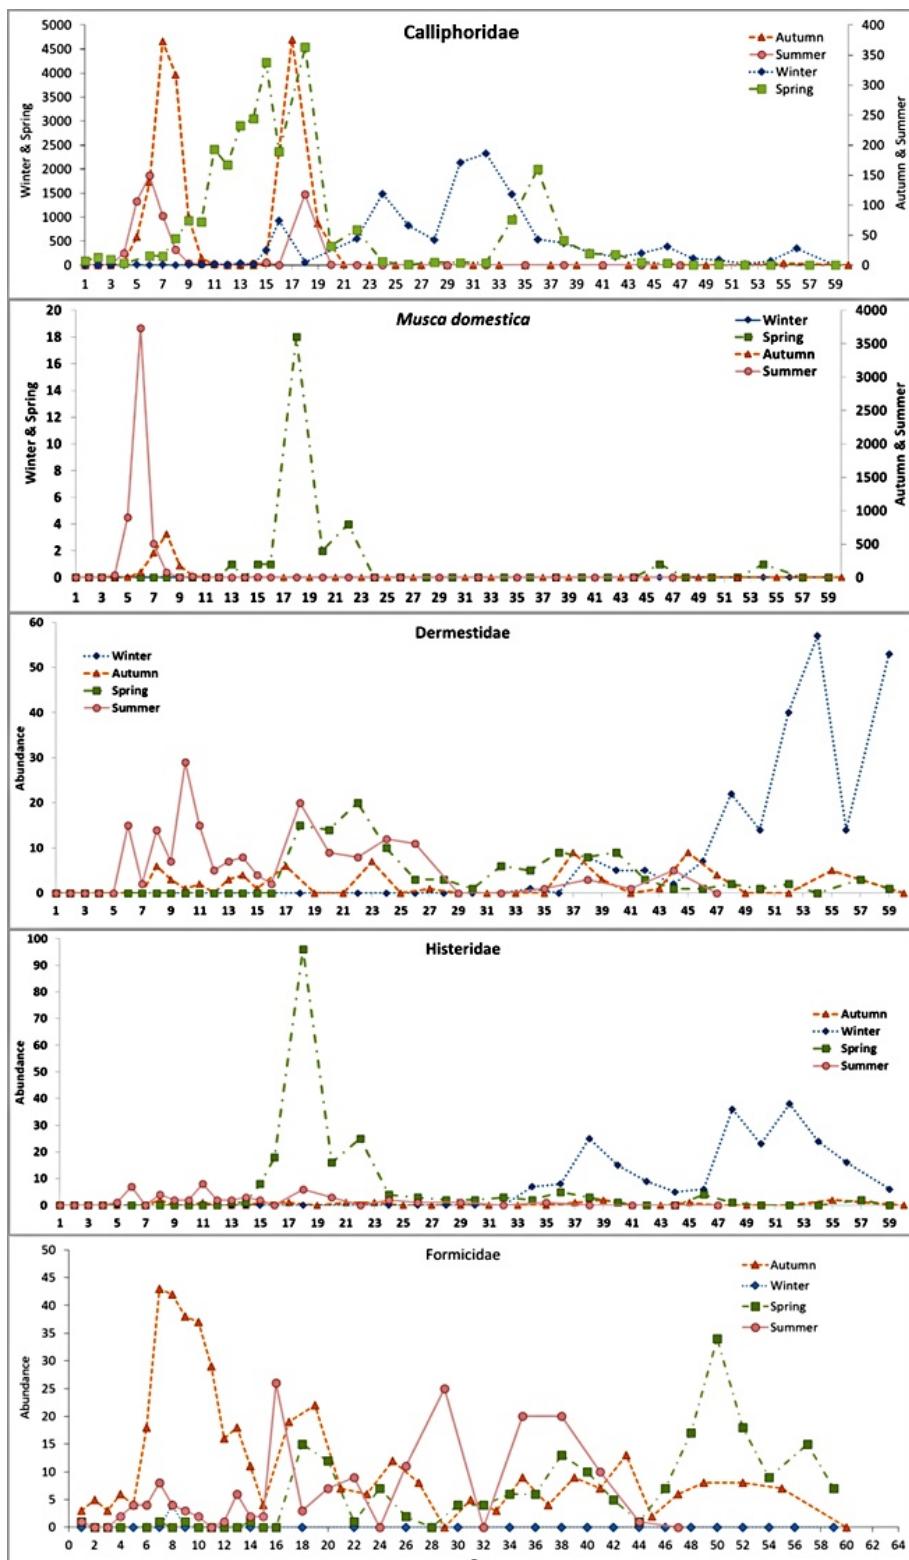

Figura S1. Abundancia y dinámica de la familia Calliphoridae, *Musca domestica*, familia Dermestidae, Histeridae y Formicidae durante las cuatro estaciones muestreadas.
